

Observed and adjusted CO2 emissions, 1990-2019

Record-low coal consumption in 2019

Last year, Danish consumption of coal fell by almost 43%, and now accounts for just 5% of the observed energy consumption. Energy consumption fell by 3.4%, while observed CO₂ emissions from energy consumption fell by almost 6%. These are highlights from the preliminary energy statistics for 2019 published by the Danish Energy Agency today.

In the almost 50 years over which the Danish Energy Agency has been collecting energy statistics, the Agency has never registered a lower consumption of coal and coke in Denmark than in 2019, when observed consumption amounted to 39 PJ. This corresponds to just 5% of energy consumption. Coal consumption fell by 42.7% compared with 2018, while consumption of natural gas fell by 7.6%.

This trend is due to a general drop in observed energy consumption of 3.4%, increasing net imports of electricity from neighbouring countries, as well as higher consumption of renewable energy. Renewables covered 35.0% of the *observed energy consumption* in 2019, compared with 32.9% in 2018.

Drop in CO₂ emissions from energy consumption

There was high wind energy production in 2019, and combined with the falling consumption of fossil fuels, this meant that observed CO₂ emissions from energy consumption dropped last year by 5.7% compared with 2018. Adjusted for climate fluctuations and fuel consumption linked to foreign trade in electricity, CO₂ emissions fell by 3.9% in 2019.

Since 2010, observed CO₂ emissions from energy consumption have fallen by 34.1%, and adjusted emissions have been reduced by 22.6%.

Drop in oil and natural gas production

Primary energy production in Denmark fell last year by 10.3% as a result of a dramatic fall in the production of oil and natural gas of 11.4% and 25.7%, respectively. Production from the North Sea in recent years has shown a downward trend, but the temporary shutdown and redevelopment of the Tyra field from September 2019 and to the completion in 2022 has particularly affected gas production from Tyra and production and landfall transportation from a number of associated fields.

On the other hand, production of renewables has moved in the opposite direction, with an increase of 4.2%, corresponding to 7.2 PJ. The increase in the production of renewable energy is primarily due to an increase in production of wind power and biogas.

[See table of the preliminary Energy Statistics 2019 \(Excel file\).](#)

Other results:

- Observed Danish energy consumption fell by 3.4% to 724 PJ in 2019. Consumption of coal and natural gas decreased in 2019, by 42.7% and 7.6%, respectively, while consumption of oil and renewables etc. increased by 0.8% and 2.8%, respectively.
- Adjusted gross energy consumption fell in 2019 by 2.0% to 766 PJ, with a drop in coal and natural gas of 26.3% and 4.7%, respectively. Consumption of renewable energy increased by 4.9%, while consumption of oil rose by 0.9%.
- Energy intensity measured in relation to adjusted gross energy consumption fell by 3.9% in 2019 compared with 2018. A drop in intensity means that gross domestic product has risen by more than energy consumption.
- A preliminary estimate indicates that the total Danish *observed* emissions of greenhouse gases (including emissions of nitrous oxide and

methane from agriculture, excluding the LULUCF sectors soil and forests) fell by 4.1% in 2019. A final statement of Danish emissions of greenhouse gases will be published later by DCE - the Danish Centre for Environment and Energy.
